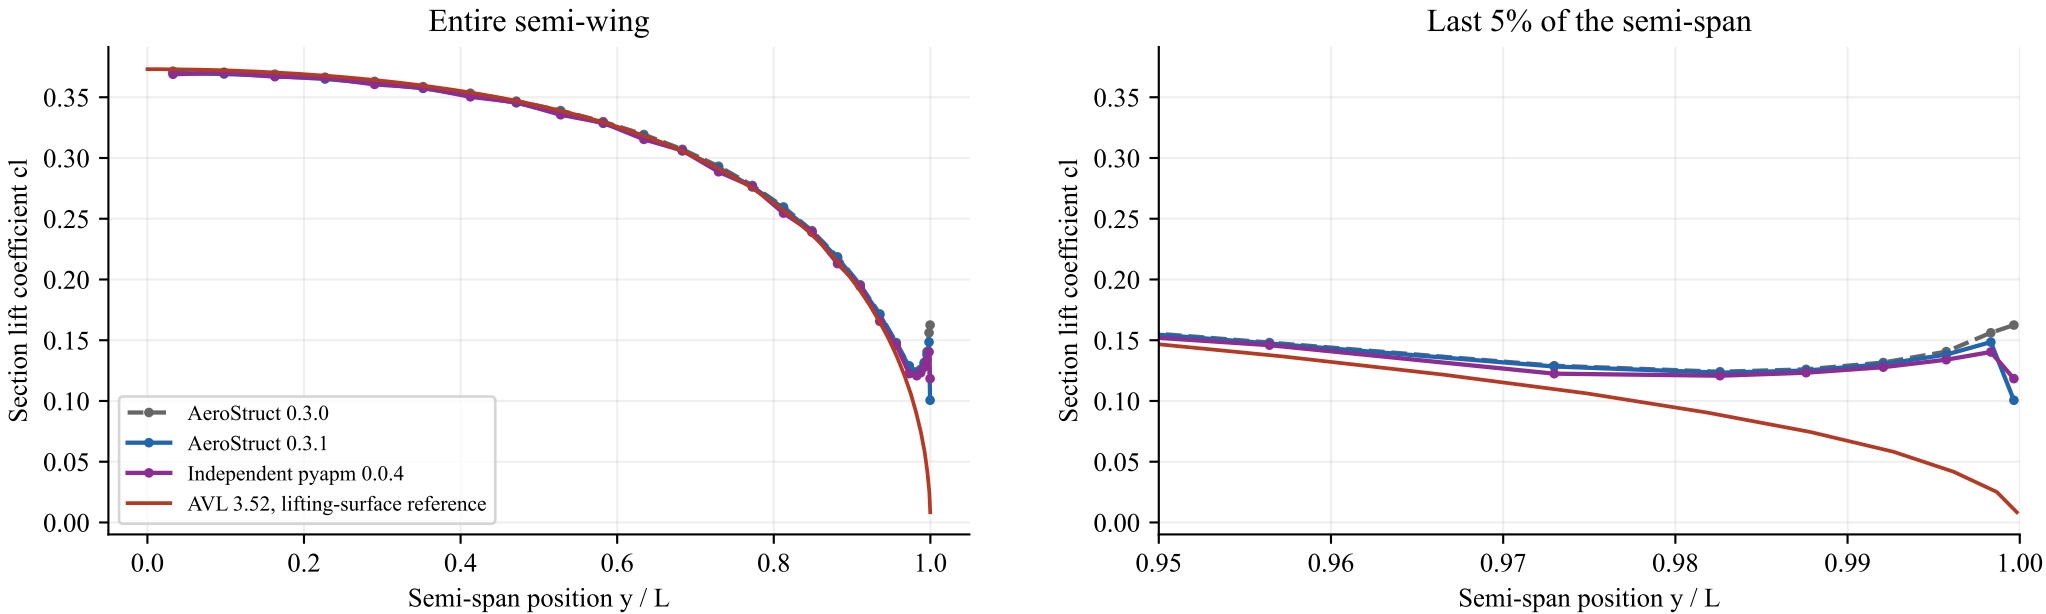
# The same wing in two independent thick-surface panel solvers

NACA 0012 | AR 6 | half-span 600 mm, chord 200 mm | alpha 4 deg | V = 10 m/s



AeroStruct and pyapm: identical rounded-tip surface mesh, 32 chordwise panels per surface, 24 requested spanwise strips.
Both thick-surface implementations show a local tip-load upturn. Local tip pressure remains unvalidated.
AVL uses a lifting surface with an independently measured XFOIL lift-slope correction and does not resolve tip thickness.

pyapm pressure drag is negative on this mesh: its local Cp is not a validated reference. Raw samples; no smoothing or clipping.
